# CS 181 Spring 2024 Section 8 Bayesian Networks and Inference

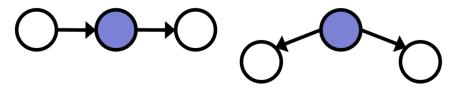

#### 1 Bayesian Networks

A Bayesian network is a graphical model that represents random variables and their dependencies using a directed acyclic graph. Bayesian networks are useful because they allow us to efficiently model joint distributions over many variables by taking advantage of the local dependencies. With Bayesian networks, we can easily reason about conditional independence and perform inference on large joint distributions.

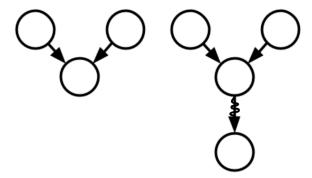

#### 1.1 D-separation rules

Let  $X_A$  and  $X_B$  denote sets of variables that we are interested in reasoning about.  $X_A$  and  $X_B$  are *d-separated* by a set of evidence  $X_E$  if **every** undirected path from  $X_A$  to  $X_B$  is "blocked" by  $X_E$ . A path is blocked by evidence  $X_E$  if EITHER:

1. There is a node Z with non-converging arrows on the path, and  $Z \in X_E$ . The shaded node indicates an evidence node.

2. There is a node Z with converging arrows on the path, and neither Z nor its descendants are in  $X_E$ .

Make sure to check **every** undirected path from  $X_A$  to  $X_B$ . Within each path, only one node Z needs to fall under one of the two cases described above for the whole path to be blocked.

If  $X_A$  and  $X_B$  are d-separated by  $X_E$  (i.e., all paths are blocked), then  $X_A$  and  $X_B$  are conditionally independent given  $X_E$  ( $X_A \perp X_B \mid X_E$ ).

#### 2 Network Basics

A patient goes to the doctor for a medical condition, and the doctor suspects 3 diseases as the cause of the condition. The 3 diseases are  $D_1$ ,  $D_2$ , and  $D_3$ , and they are independent from each other (given no other observations). There are 4 symptoms  $S_1$ ,  $S_2$ ,  $S_3$ , and  $S_4$ , and the doctor wants to check for presence in order to find the most probable cause.  $S_1$  can be caused by  $D_1$ ,  $S_2$  can be caused by  $D_1$  and  $D_2$ ,  $S_3$  can be caused by  $D_1$  and  $D_3$ , and  $S_4$  can be caused by  $D_3$ . Assume all random variables are Bernoulli, i.e. the patient has the disease/symptom or not.

• Q: Draw a Bayesian network for this problem with the variable ordering  $D_1, D_2, D_3, S_1, S_2, S_3, S_4$ .

• Q: Write down the expression for the joint probability distribution given this network.

• Q: How many parameters are required to describe this joint distribution?

• Q: How many parameters would be required to represent the CPTs in a Bayesian network if there were no conditional independences between variables?

• **Q:** What diseases do we gain information about when observing the fourth symptom  $(S_4 = true)$ ?

• Q: Suppose we know that the third symptom is present  $(S_3 = true)$ . What does observing the fourth symptom  $(S_4 = true)$  tell us now?

### 3 D-Separation

As part of a comprehensive study of the role of CS 181 on people's happiness, we have been collecting important data from students. In an entirely optional survey that all students are required to complete, we ask the following highly objective questions:

Do you party frequently [Party: Yes/No]?

Are you smart [Smart: Yes/No]? Are you creative [Creative: Yes/No]?

Did you do well on all your homework assignments? [HW: Yes/No]

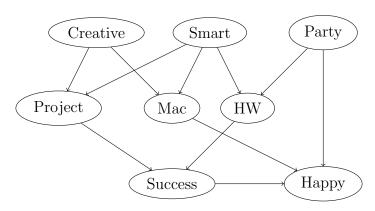

Do you use a Mac? [Mac: Yes/No]

Did your last major project succeed? [Project: Yes/No]

Did you succeed in your most important class? [Success: Yes/No]

Are you currently Happy? [Happy: Yes/No]

After consulting behavioral psychologists we build the following model:

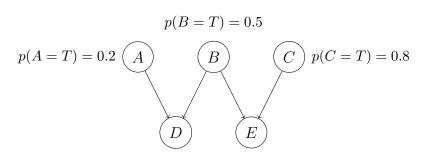

- Q: True or False: Party is independent of Success given HW.
- Q: True or False: Creative is independent of Happy given Mac.
- Q: True or False: Party is independent of Smart given Success.

•	Q: True	or False:	Party is	independent	of $C$	reative	given	Happy.
---	---------	-----------	----------	-------------	--------	---------	-------	--------

 $\bullet~\mathbf{Q:}$  True or False: Party is independent of Creative given Success, Project and Smart.

## 4 Inference

Consider the following Bayesian network, where all variables are Bernoulli.

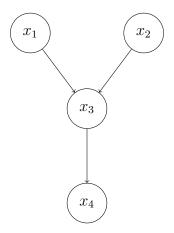

A	B	p(D = T A, B)	B	C	p(E = T B, C)
$\overline{F}$	F	0.9	$\overline{F}$	$\overline{F}$	0.2
F	T	0.6	F	T	0.4
T	F	0.5	T	F	0.8
T	T	0.1	T	T	0.3

• Q: What is the probability that all five variables are simultaneously false (F)?

• Q: What is the probability that A is false given that the remaining variables are all known to be true (T)?

#### 5 Variable Elimination in Bayesian Networks

We apply an inference algorithm called variable elimination to the following Bayesian network:

Assume that all of the random variables are Bernoulli, meaning their domain is  $\{0,1\}$  with domain size k=2. In this network, we can encode the joint distribution as

$$p(x_1, x_2, x_3, x_4) = p(x_1)p(x_2)p(x_3|x_1, x_2)p(x_4|x_3)$$

If we wanted to calculate the marginal distribution of  $x_4$  that is, have  $x_4$  be our query without any evidence (conditioned on variables), we could naively marginalize out all other variables:

$$p(x_4) = \sum_{x_1} \sum_{x_2} \sum_{x_3} p(x_1, x_2, x_3, x_4)$$
$$= \sum_{x_1} \sum_{x_2} \sum_{x_3} p(x_1) p(x_2) p(x_3 | x_1, x_2) p(x_4 | x_3)$$

To calculate these sums, for each value of  $x_4$ , we would need to do a sum-product that involves summing over the  $k^3 = 8$  possible combinations of  $x_1$ ,  $x_2$ , and  $x_3$ . In general, the number of combinations grows exponentially in the number of variables  $(O(k^n))$  if you're familiar with big-O notation).

Note that Bayesian nets encode dependencies between variables, which we can use to calculate the marginal distribution more efficiently. By reordering the sums and eliminating

one variable at a time, we derive the variable elimination procedure:

$$p(x_4) = \sum_{x_1} \sum_{x_2} \sum_{x_3} p(x_1) p(x_2) p(x_3 | x_1, x_2) p(x_4 | x_3)$$

$$= \sum_{x_3} p(x_4 | x_3) \sum_{x_2} p(x_2) \sum_{x_1} p(x_3 | x_1, x_2) p(x_1)$$

$$= \sum_{x_3} p(x_4 | x_3) \sum_{x_2} p(x_2) p(x_3 | x_2)$$

$$= \sum_{x_3} p(x_4 | x_3) p(x_3)$$

$$= p(x_4)$$

Here, we eliminate  $x_1$  using a k by k matrix  $g_1(x_3, x_2)$ , because we have to sum over  $x_1$  for each possible value of  $x_2$  and  $x_3$ . Then we eliminate  $x_2$  with a K-dimensional vector  $g_2(x_3)$ , likewise because we sum over  $x_2$  for each possible value of  $x_3$ . Lastly, we eliminate  $x_3$ , which results in a final K-dimensional vector of probabilities for  $x_4$ . Notice that we have a poly-tree, and we're eliminating leaves first and working towards our query variable,  $x_4$ .

In this way, we can perform the same computation in  $O(k^3)$  time, because the longest elimination step has to do  $k^2$  sum-product calculations for each element in the matrix  $g_1(x_3, x_2)$ , and each sum-product calculation takes O(k) time (since we are summing over  $x_1$ ). Compare this polynomial-time complexity (where we add the time taken for each elimination step, so our total time complexity only depends on the longest step) with the exponential-time complexity (based on the number of variables) of the naive approach.

Alternatively, we could have eliminated variables in a different order:

$$p(x_4) = \sum_{x_1} \sum_{x_2} \sum_{x_3} p(x_1) p(x_2) p(x_3 | x_1, x_2) p(x_4 | x_3)$$

$$= \sum_{x_1} p(x_1) \sum_{x_2} p(x_2) \sum_{x_3} p(x_3 | x_1, x_2) p(x_4 | x_3)$$

$$= \sum_{x_1} p(x_1) \sum_{x_2} p(x_2) p(x_4 | x_1, x_2)$$

$$= \sum_{x_1} p(x_1) p(x_4 | x_1)$$

$$= p(x_4)$$

Here, we eliminate  $x_3$ , then  $x_2$ , then  $x_1$ . Notice that the ordering matters: eliminating  $x_3$  first results in a  $k \times k \times k$  object  $g(x_1, x_2, x_4)$ , so our overall algorithm will run in  $O(k^4)$  time. (Again, note that we have to account for both the  $k^3$  sum-product calculations and the O(k) time to do each calculation.)

In general, the computational cost of variable elimination depends on the number of variables in these intermediate factors, in particular the largest object computed ('treewidth').

#### 5.1 Exercise: Variable Elimination

Consider the Bayesian network described in above, and assume the following Conditional Probability Table (CPT). Let  $x_i \in \{0,1\}$  denote the values that variable  $X_i$  can take. Our goal is to find  $p(x_4)$ .

$x_1$	$p(x_1)$	$x_2$	$p(x_2)$
0	0.3	0	0.6
1	0.7	1	0.4

$x_3$	$x_1$	$x_2$	$p(x_3 x_1,x_2)$
0	0	0	0.5
0	0	1	0.2
0	1	0	0.9
0	1	1	0.5
1	0	0	0.5
1	0	1	0.8
1	1	0	0.1
1	1	1	0.5

$x_4$	$x_3$	$p(x_4 x_3)$
0	0	0.7
0	1	0.1
1	0	0.3
1	1	0.9

- 1. Eliminate  $X_1$  first. Draw the resulting Bayesian network and compute the CPT.
- 2. Eliminate  $X_3$  first. Draw the resulting Bayesian network and compute the CPT.
- 3. How many sum-product calculations do each of these variable elimination orders require? Which one is preferable?
